ABSTRACT

An endotracheal tube holder is provided. The tube holder allows adjustment of the position of an endotracheal tube during use. In some embodiments the tube holder comprises a body portion, wherein the body portion is elongated and comprises an elongated opening. The tube holder also comprises a tube grasping mechanism and an attachment mechanism for adjustably securing the tube grasping mechanism to the body portion. The attachment mechanism comprises a rod member configured to pass through the elongated opening, a widened proximal body connected to a proximal end of the rod member; and a widened distal body attached to a distal end of the rod member, having a size that prevents the widened distal body from passing through the elongated opening to secure the attachment mechanism to the body portion.

ENDOTRACHEAL TUBE HOLDER**PRIORITY**

This application claims priority under 35 U.S.C. §119 to U.S. Provisional Patent Application No. 61/410,979, which was filed on Nov. 8, 2010, and is herein incorporated by reference.

FIELD

The present disclosure relates to tube holders, and more specifically, to endotracheal tube holders.

Endotracheal tubes are used in a variety of settings including in critical care, intensive care units, or under general anesthesia. However, most endotracheal tube holders only allow an endotracheal tube to be held in a single, fixed position, which can create problems, especially during long term use. The present disclosure provides endotracheal tube holders that allow easy adjustment of the position of an endotracheal tube either before or during use.

SUMMARY

One embodiment consistent with the present disclosure includes an endotracheal tube holder. The endotracheal tube holder comprises a body portion, wherein the body portion is elongated and comprises an elongated opening. The endotracheal tube holder also comprises a tube grasping mechanism, and an attachment mechanism for adjustably securing the tube grasping mechanism to the body portion. The attachment mechanism comprises a rod member configured to pass through the elongated opening, a widened proximal body connected to a proximal end of the rod member, and a widened distal body attached to a distal end of the rod member, having a size that prevents the widened distal body from passing through the elongated opening to secure the attachment mechanism to the body portion.

In certain embodiments of the present disclosure, the elongated opening includes a wide opening for receiving the widened distal body. In certain embodiments, the widened distal body has a spring like property along at least one dimension configured to being forcibly pushed through the wide opening and for locking behind the body portion. Moreover, in certain embodiments, the widened distal body has a spring like property along at least one dimension configured to being forcibly pushed through a section of the elongated opening and for locking behind the body portion.

In certain embodiments of the present disclosure, the rod member comprises a threaded rod. In certain embodiments, at least one of the widened proximal body and the widened distal body includes a threaded locking cap such that rotation of the locking cap with respect to the threaded rod changes a distance between the widened proximal body and the widened distal body to clamp or release the attachment mechanism to or from the body portion.

In certain embodiments of the present disclosure, the tube grasping mechanism comprises a widened end surface in which a middle opening is formed for receiving the rod member, wherein the rod member is rigidly connected to the widened distal body at the distal end, and wherein the widened proximal body includes the locking cap, such that the threaded rod passes through the elongated opening and the middle opening and is threadably connected to the locking cap.

In certain embodiments of the present disclosure, the tube grasping mechanism comprises a widened end surface in

2

which a middle opening is formed for receiving the rod member, wherein the widened end surface is for attaching to the body portion, and wherein the widened proximal body and the widened distal body sandwich between them the body portion and the widened end surface. In certain embodiments, the body portion is curved for conforming to the shape of the face of a patient.

In certain embodiments, the tube grasping mechanism comprises an upper semicircular region and a lower semicircular region pivotably attached to the upper semicircular region. In certain embodiments, the upper semicircular region and the lower semicircular region comprise teeth to lock the lower semicircular region to the upper semicircular region and secure a tube therebetween. In certain embodiments, the lower semicircular region includes a tail end and the upper semicircular region includes a pincer configured to receive and lock the tail end and accordingly secure a tube between the upper and the lower semicircular regions. In certain embodiments, the tail end is toothed on at least one surface.

In certain embodiments, the body portion further comprises widened pad regions at opposite ends for lying against the face of a patient. In certain embodiments, the tube holder further comprises a band opening on each of the widened pad regions for receiving a flexible band for tying around the head or the neck of the patient.

In certain embodiments, the tube holder further comprises an arm that connects the tube grasping mechanism to the attachment mechanism. In certain embodiments, the elongated opening includes a toothed surface on at least one side.

Another embodiment consistent with the present disclosure includes an endotracheal tube holder which comprises a body portion, wherein the body portion is elongated and comprises an elongated opening, and a tube grasping mechanism rigidly connected to an attachment mechanism for adjustably securing the tube grasping mechanism to the body portion. In certain embodiments, the attachment mechanism comprises a rod member that passes through the elongated opening, and widened surfaces attached to the opposite sides of the rod member, which install on opposite sides of the elongated opening form a clamping mechanism for securing the tube grasping mechanism to the body portion.

In certain embodiments, the rod member comprises a threaded body that is connected at least one end to a threaded locking cap such that rotation of the locking cap with respect to the rod member changes a distance between the widened surfaces on opposite sides of the elongated opening to clamp or release the attachment mechanism.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate exemplary embodiments consistent with the principles of the present invention.

FIG. 1 provides a prospective view of an endotracheal tube holder, according to certain embodiments of present disclosure.

FIG. 2 provides a rear view of the endotracheal tube holder of FIG. 1.

FIG. 3 provides a side view of the endotracheal tube holder of FIG. 1.

FIG. 4 provides a front view of the endotracheal tube holder of FIG. 1.

FIG. 5 provides a bottom view of the endotracheal tube holder of FIG. 1.

3

FIG. 6 provides a side cutaway view of an attachment mechanism of endotracheal tube holders, according to exemplary embodiments.

FIG. 7 provides a rear view of an endotracheal tube holder, according to certain embodiments of present disclosure.

FIG. 8 shows an exploded view of an endotracheal tube holder according to certain embodiments of present disclosure.

FIG. 9 shows a front view of a body portion of the endotracheal tube holder of FIG. 8.

FIG. 10 shows detailed side views of a grasping mechanism and an attachment mechanism of the endotracheal tube holder of FIG. 8.

FIG. 11 shows a view of an assembled endotracheal tube holder holding a tube against the face of a patient, according to certain embodiments of present disclosure.

DETAILED DESCRIPTION

The present disclosure provides endotracheal tube holders that will allow adjustment of the position of an endotracheal tube either before or during use. FIG. 1 provides a perspective view of an endotracheal tube holder 10, according to certain embodiments. As shown, the endotracheal tube holder 10 includes an elongated body portion 20, a tube grasping mechanism 30, and an attachment mechanism 40 for adjustably securing the tube grasping mechanism 30 to the body portion 20.

As shown in FIG. 1, the elongated, body portion 20 can include an elongated opening 50 that extends along the length of the curved body portion. The elongated opening 50 can be configured to engage with the attachment mechanism 40 to secure the tube grasping mechanism 30 to the elongated, body portion 20. The body portion 20 can be formed from a variety of different materials. In some embodiments the body portion 20 is formed from a rigid material selected to maintain its curved shape during use. The rigid material may have a curvature selected to conform to the shape of a patient's face to allow comfortable placement of the endotracheal tube holder 10.

The body portion 20 can also include additional components that allow comfortable attachment to a patient. For example, the body portion 20 can include two enlarged pad regions 55 at opposite ends. The enlarged pad regions 55 provide a widened surface area for placement against the patient's body, e.g., against the patient's cheeks or head. In addition the endotracheal tube holder can include regions for attachment to a band of flexible material. For example, in certain embodiments the endotracheal tube holder includes band openings 60 located at opposite ends. The band openings 60 can receive a band such as a flexible elastic band, tape or other material to secure the endotracheal tube holder to a patient. In addition, the pad regions can include an adhesive or tacky surface that prevents movement or sliding, and may also include cushioned or padded surfaces. Moreover, in certain embodiments, the body portion 20 can further attach to an elongated pad 51. On one surface, the elongated pad 51 can attach to the back of the body portion 20. On the other surface, the elongate pad 51 attaches to the a region of the patient's face, for example, between the upper lip and the nose of the patient. In certain embodiments, the elongated pad 51 can be made of a soft material to provide a cushion against the harder surface of the body portion 20 and to provide comfort to the patient. In certain embodiments, such as those shown in FIGS. 1-5 and 7, the pad 51 is almost as long as the elongated opening 50. Moreover, in certain embodiments, the pad 51

4

includes an opening which overlaps the elongated opening 50, such that the pad 41 does not block the elongated opening 50.

As discussed above, the endotracheal tube holder 10 can include a tube grasping mechanism 30. The tube grasping mechanism allows secure attachment of an endotracheal tube 65, thereby preventing unintended movement or dislodgement. The tube grasping mechanism 30 can include a variety of different configurations. For example, as shown in FIGS. 1-5, the tube grasping mechanism 30 can include a rigid plastic or other rigid material to allow secure attachment of an endotracheal tube 65. In some embodiments, the tube grasping mechanism 30 can include an upper semi-circular region 70 to receive an endotracheal tube. The tube grasping mechanism 30 can also include a lower semi-circular region 75 and a hinge or pivot region 80 to attach the lower semi-circular region 75 to the upper semi-circular region 70. The hinge or pivot region 80 provides a pivotable connection between the lower semi-circular region 75 and the upper semi-circular region 70. The pivotable connection 80 allows the tube grasping mechanism 30 to be opened and closed to secure the endotracheal tube 65 in place.

The tube grasping mechanism can also include systems to allow secure closure of the tube grasping mechanism. For example as shown in FIGS. 2 and 4, the tube grasping mechanism 30 can include teeth 90 and 95 on the upper and lower semi-circular regions 70 and 75, respectively. The teeth 90, 95 can engage one another to allow closure with a desired degree of pressure around the endotracheal tube.

As alternatives to the tube grasping mechanism depicted in FIGS. 1-5, other tube grasping mechanisms may be used in conjunction with the body portion 20 and attachment mechanism 40. For example, the tube grasping mechanism 30 can include non-rigid closures, such as a flexible band, including VELCRO®. Alternatively, the tube grasping mechanism can simply include a flat or curved platform to which tape or other connecting materials can be applied. For example, in one embodiment, the tube grasping mechanism 30 can include one of the upper semi-circular region 70 or the lower semi-circular region 75 to receive an endotracheal tube 65, and the tube can be held in place using tape, adhesives, a rigid cap, or other connectors.

The tube grasping mechanism 30 can be connected to the attachment mechanism 40 to allow adjustable connection to the body portion 20. In some cases, the tube grasping mechanism 30 is connected to the attachment mechanism via a rigid connector or arm 105. The rigid connector or arm 105 allows the tube grasping mechanism 30 to be firmly positioned once the attachment mechanism 40 is secured in place along the body portion 20, as described further below.

As discussed above, the attachment mechanism 40 can include a system for adjustably securing the grasping mechanism 30 to the body portion 20. As shown in FIGS. 2 and 4, the elongated opening 50 provides a track along which the attachment mechanism 40 can be moved to adjust the position of an endotracheal tube 65.

FIG. 6 provides a cutaway view of an attachment mechanism 40 for adjustably securing the tube grasping mechanism 30 to the body portion 20. As shown, the attachment mechanism 40 can include a rod portion 115 that passes through the elongated opening 50 of the body portion 20. Further, in certain embodiments, the tube grasping mechanism 30 includes a widened end surface 135 attached to the end of the arm 105, which is clamped to the body portion 20 by the attachment mechanism. The attachment mechanism 40 can include a widened rod end 125 and a locking cap 150, which are positioned on opposite sides of, and clamp together, the

5

widened end surface **135** and the body portion **20**. The rod portion **115**, by passing through the elongated opening **50** and connecting to the widened rod end **125** to a locking cap **150**, forms a clamping mechanism that can releasably secure the tube grasping mechanism **30** to the body portion **20**. Further, in some cases, widened end surface **135** attaches to an upper lip **165** that serves to stabilize the attachment mechanism **40** against the body portion **20**.

The rod portion **115**, the widened rod end **125**, and the widened end surface **135** can include a variety of configurations. In some cases, the rod portion **115** includes a rod or similar elongated structure. In addition, the rod portion **115** can include a threaded body that passes through the elongated opening **50**. The threaded rod portion **115** can be connected to the widened rod end **125** and the widened end surface **135** in a variety of ways. For example, in some cases, the rod portion **115** forms a threadable (e.g., nut and bolt arrangement) connection with at least one of the widened rod end **125** and the widened end surface **135**. In some cases, as shown in FIG. 6, the rod portion **115** passes through a portion of the widened end surface **135** on the side of the attachment mechanism **40** that connects to the tube grasping mechanism **30**. The rod portion **115** can simply pass through an opening in the widened end surface **135** or can form a threaded connection with the opening and widened end surface **135**.

In addition, as described above and shown in FIG. 6, the rod portion **115** can connect to the widened rod end **125** on the opposite side of the opening **50**. The connection with the widened rod end **125** on the opposite side of the opening can be a threaded or removable connection, or can be a permanent connection. For example, the rod portion **115** and the widened rod end **125** can be formed from a single piece of material or can be joined, e.g. by sonic welding or using other suitable joining mechanisms such as adhesives, chemical bonding, or snap fit connections.

The attachment mechanism **40** can include a system to allow the widened rod end **125** and the locking cap **150** to clamp to the body portion **20** and the widened end surface of the tube grasping mechanism **30**. For example, as shown, the dimensions of the widened rod end **125** and the locking cap **150**, and also the dimensions of the widened end surface **135** and the upper lip **165**, prevent them from passing through the elongated opening **50**. In addition, force can be applied to the widened rod end **125** and the widened end surface **135** to allow the surfaces to clamp the body portion and hold the body portion **20** in place. For example, as shown in FIG. 6, the locking cap **150** can be a threaded locking cap. The locking cap **150** can include a threaded inner portion **155** that engages an end of the rod portion **115**. Rotation of the locking cap **150** with respect to the rod portion **115**, which can include a threaded outer surface, will change the distance between the widened rod end **125** and the widened end surface **135** to clamp or release the attachment mechanism **40** to the body portion **20**. Moreover, in some embodiments, the widened rod end **125** and body portion **20** are selected such that friction between their surfaces prevents widened rod end **125** and the rod portion **115** from rotating when the locking cap **150** is rotated. Accordingly, the position of the attachment mechanism **40** along the elongated opening **50** of the curved body can be adjusted, and the attachment mechanism **40** can be tightened to clamp the attachment mechanism **40** and tube grasping mechanism **30** in place. In various embodiments, the widened rod end **125** and the widened end surface **135** and body portion **20** can be selected to produce sufficient friction to prevent movement of the tube grasping mechanism **30** when the attachment mechanism is locked or clamped in a selected position.

6

FIG. 7 provides a rear view of an endotracheal tube holder, according to certain embodiments of present disclosure. The endotracheal tube holder **10'** of FIG. 7 is similar to the tube holder **10** described above. However, in some cases, as pointed out in FIG. 7, the elongated opening **50'** of the body portion **20** can include surface configurations to stabilize the attachment mechanism. For example, as shown, at least one edge of the elongated opening can include curves or teeth **145**. The curves or teeth can conform to the shape of the rod portion **115** to receive the rod portion **115** and prevent sliding of the attachment mechanism **40**. In various embodiments, the teeth or the curves can be of various sizes, which can depend on the size of the tube or the specific use.

FIG. 8 shows an exploded view of an endotracheal tube holder **800** according to certain embodiments. Endotracheal tube holder **800** can include at least three parts: a body portion **820**, a tube grasping mechanism **830**, and an attachment mechanism **840**. When assembled, attachment mechanism **840** attaches tube grasping mechanism **830** to body portion **820**. Unless stated otherwise, different sections of the endotracheal tube holder **800** are designed and function in a manner similar to the corresponding sections of other embodiments described in FIGS. 1-7.

FIG. 9 shows a front view of the body portion **820** of FIG. 8. The body portion **820** includes an elongated middle section **825**, two enlarged pad regions **855** attached to the opposite ends of the middle section **825**, and two band openings **860** attached to the two pad regions **855**. Middle section **825** includes an elongated opening **850**. In certain embodiments shown in FIGS. 8 and 9, the elongated opening **850** is in the form of an elongated slit for directing the attachment mechanism **840** to which the tube grasping mechanism **830** is attached. Also, in certain embodiments, the elongated opening **850** widens at one end, forming a wide opening **852**. The remainder of the elongated opening **850**, i.e., slit **853**, is narrower than the wide opening **852**. In FIGS. 8 and 9, wide opening **852** is in the form of an open circle. In various embodiments, the opening can have other shapes, such as open oval or rectangular. In some embodiments, wide opening **852** is sized for receiving the attachment mechanism **840**, and the narrow slit **853** is configured for holding and leading that mechanism, as explained below in more detail.

FIG. 10 shows detailed side views of the grasping mechanism **830** and the attachment mechanism **840** of FIG. 8. The tube grasping mechanism **830** includes an upper lip **865**, a widened end surface **835**, an arm **837**, upper and lower semicircular regions **870** and **875**, and locking lever **878**.

In some embodiments, the upper and lower semicircular regions **870** and **875**, and the locking lever **878** provide a tube-locking mechanism to receive and secure a tube. For example, in certain embodiments, the lower semicircular region **875** includes a lower handle **876** and end section **877**. Moreover, the locking lever **878** includes a lever handle **879**. In some embodiments, the region attaching the upper and lower semicircular regions **870** and **875** is made of a flexible material. When using the tube holder, to receive a tube, a user inserts the end section **877** through the gap **881** by, for example, pulling lever **878** away and opening the gap **881**. The user thus creates a tube receiving area between the upper and lower semicircular regions **870** and **875**. The user can then insert the tube into the tube receiving area. If the area is too narrow for receiving a selected tube, a user can widen the tube receiving area by moving the lower semicircular region **875** away from the upper semicircular region **870** using, for example, the lower handle **876**. Similarly, to tighten the tube receiving area around the tube, a user can narrow the tube-receiving area by pushing the lower semicircular region **875**

towards the upper semicircular region **870** using, for example, the lower handle **876** or by pushing the lower semicircular region **875** from below. As a result of these narrowing or widening actions, the end section **877** moves up or down through the gap **881**.

In some embodiments, the locking lever **878** can lock the end section **877** and secure the tube in place. In the embodiment shown in FIG. **10**, for example, the outer surface of end section **877** is toothed. Further, the locking lever **878** and the area attaching this lever to the arm **837** can be made of flexible materials with spring-like characteristics, such as a living hinge. The locking lever **878** and the left half of upper semicircular region **870** thus create a pincer that can lock the end section **877** in place. When the user releases the lever handle **879**, the lever **878** moves back in, such that the end of lever **878** engages the teeth on the outer surface of end section **877** and locks the pincer on the end section **877**. In various embodiments, the length of the toothed section the end section **877** varies, to enable the tube grasping mechanism **830** to secure tubes of various sizes.

Using the above mechanism, a user can insert and lock a tube in endotracheal tube holder **800**. The user locks the tube by narrowing the tube receiving area to a size that is snug fit to the tube and then locking the end section **877** with the lever **878**. In some embodiments, the inner surface of the upper semicircular region **870** or the lower semicircular region **875** includes a rough surface to create friction with the tube and thus prevent the tube from slipping through the tightened receiving area. In some embodiments, one or both the inner surfaces of the semicircular regions includes some grabbing teeth for creating the friction.

FIGS. **8** and **10** also show some details of the attachment mechanism **840**, according to some embodiments. This attachment mechanism includes a knob handle **842**, a knob cap **843**, a middle rod **844**, and a bulge **845**. In some embodiments, the attachment mechanism **840** is a unitary piece, in which the parts, that is, the knob handle **842**, the knob cap **843**, the middle rod **844**, and the bulge **845** are fixed to each other. In some embodiments, these parts are made as one piece using one mold.

When assembling the endotracheal tube holder **800**, an assembler can use the attachment mechanism **840** to attach the tube grasping mechanism **830** to the body portion **820**. In some embodiments, the diameter of bulge **845** is almost equal to or slightly less than the diameter of the wide opening **852** and is larger than the width of the narrow slit **853**. The diameter of the middle rod **844**, on the other hand, is almost equal or smaller than the width of the narrow slit. The diameter of the bulge **845** is also smaller than or almost equal to the dimension of the middle opening **836** in the center of the end surface **835**. In these embodiments, the assembler needs little or no force to pass the bulge **845** first through the middle opening **836** and then through the wide opening **852**.

Further, in certain embodiments, a disassembler can disassemble the endotracheal tube holder **800**. To disassemble the endotracheal tube holder **800**, in certain embodiments, the disassembler can remove the attachment mechanism **840** from the body portion and the grasping mechanism. To do that, the disassembler moves the attachment mechanism to the end of the narrow slit **853** where the wide opening **852** is located, such that bulge **845** is positioned behind wide opening **852**. The disassembler then removes the attachment mechanism by respectively pulling out the bulge **845** through the wide opening **852** and the middle opening **836**. In certain other embodiments, once assembled and in the normal course of use, the endotracheal tube holder **800** will not be disassembled.

In some embodiments, the bulge **845** is made of a flexible material, and its diameter is slightly larger than the width of the wide opening **852**. Moreover, as shown in FIG. **10**, in some embodiments the bulge **845** includes an open slit in the middle. In some embodiment, due to the open slit or its spring-like characteristics, the bulge also possesses a spring like characteristic along a diameter perpendicular to the slit, such that it collapses when pinched and returns to its original size when the pinching force is removed. In these embodiments, the assembler first passes bulge **845** through the middle opening **836** and then, to pass the bulge through wide opening **852**, the assembler has to use some force. Due to its spring like characteristics, when pinched or pushed into the wide opening **852**, bulge **845** shrinks, passes through the wide opening **852**, and then opens up. In this manner, due to its size, bulge **845** locks behind the wide opening **852**.

Further, in certain embodiments, a disassembler can disassemble the endotracheal tube holder **800**. In certain embodiments, to disassemble the endotracheal tube holder **800**, the disassembler first moves the attachment mechanism to the end of the narrow slit **853** where the wide opening **852** is located, such that bulge **845** is positioned behind wide opening **852**. Further, to pull the bulge out of the wide opening **852**, the disassembler can first press the bulge **845** to a smaller size before moving through wide opening **852**. The disassembler then removes the attachment mechanism by pulling out the bulge **845** through the wide opening **852** and the middle opening **836**. In certain other embodiments, once assembled and in the normal course of use, the endotracheal tube holder **800** will not be disassembled.

In some embodiments, the elongated opening **850** does not include a wide opening. In these embodiments, the assembler can press the bulge through the elongated opening or the disassembler may remove the bulge from the elongated opening by shrinking the bulge using the force of pressing or by a pinching force. In various embodiments, an assembler or a disassembler can be a technician or a machine in the manufacturing factory, a technician in the medical facility, or any other end user.

In some embodiments, when using the assembled endotracheal tube holder **800**, the user moves the grasping mechanism **830** and the attachment mechanism **840** along the middle section **825**. During these movements, the middle rod **844** moves through narrow slit **853**. In these situations, bulge **845**, which is larger than narrow slit **853**, holds the attachment mechanism attached to the middle section **825**. When the user moves the grasping mechanism **830** to a desired position, the user then secures the grasping mechanism in place by tightening the attachment mechanism **840** such that it clamps the middle section **825** of body portion **820** to the widened end surface **835** of the tube grasping mechanism **830**.

In some embodiments, the user performs the tightening by turning knob handle **842** in one direction, and performs the untightening and thus unclamping by turning the knob handle **842** in the opposite direction. The tightening and untightening are achieved by a set of tightening features included in the widened end surface **835** of the tube grasping mechanism **830** and the knob cap **843** of the attachment mechanism **840**.

In some embodiments, as shown in FIG. **10**, the tightening features of the widened end surface **835** are included in the a protruded surface **831** located at the front surface of the widened end surface **835**. These tightening features of the protruded surface **831** include a tightening groove **832** formed on its surface. The tightening features also include a cut out of the lower right side of the protruded surface **831**, as shown in FIG. **10**. This lower right cut out covers approximately one fourth of the perimeter of the protruded surface

831 and creates two stopper teeth at its two end points shown in FIG. **10**; a lower stopper tooth **833** located approximately at the lowest point on the perimeter of the protruded surface **831**, and a side stopper tooth **834** located approximately at the right-most point on that perimeter.

The tightening features of the knob cap **843** can be included on the rear surface of the knob cap **843**. These features include a tension tang **846** and a positive stopper **847**.

When the assembler assembles the three parts of the endotracheal tube holder **800**, that is, the body portion **820**, the tube grasping mechanism **830**, and the attachment mechanism **840**, the tightening features of inner surface of the knob cap **843** fit against the tightening features of the protruded surface **831**. For example, in the embodiments shown in FIG. **10**, the assembler lays the widened end surface **835** of the tube grasping mechanism against the middle section **825** of the body portion, such that the upper lip **865** lies over the upper edge of the middle section **825**. Moreover the assembler lines up the middle opening **836** with the wide opening **852**. The assembler then orients the attachment mechanism **840** such that knob handle **842** is in “open” position, that is the knob handle is approximately parallel to the outer edges of the end surface **835** as, for example, shown in FIG. **10**. The assembler then attaches the attachment mechanisms to the end surface **835** and the middle section **825** that have been laid together, by passing the bulge **845** through the middle opening **836** and through the wide opening **852**.

In the assembled configuration, the attachment mechanism **840** sandwiches together the body portion **820** and the grasping mechanism **830**. In particular, a clamping mechanism is formed by three pieces, the bulge **845** as the rear end, the knob cap **843** as the front end, and the middle rod **844** connecting these two ends. The two clamping ends sandwich between them two sandwiched surfaces, that is, the middle section **825** of the body portion and the widened end surface **835** of the tube grasping mechanism. The length of the middle rod **844** is such that in the assembled configuration and when the knob is in the open position, the space between the two ends of the clamp is almost the same as the combined thickness of the sandwiched surfaces. Therefore, in this position, the protruded surface **831** attaches to the inner surface of the knob cap **843**. The length of the middle rod **844** is also such that in the open position of the knob, the clamp ends do not press the sandwiched surfaces too tightly, allowing them to move freely against each other.

Upon such attachment, tightening features of the two surfaces fits against each other. For example, tension tang **846** fits in the upper portion of the groove **832** and stopper **847** fits inside the lower right cut out next to the lower stopper tooth **833**. Because the pieces are not tightly clamped in this situation, a user can move the tube grasping mechanism **830** along the middle section **825** by moving the middle rod **844** inside the elongated opening **850**. After moving the tube grasping mechanism to the desired position, the user can secure it in place by tightening the clamping mechanism. In the embodiment shown in FIG. **10**, the user tightens the clamping mechanism by turning knob handle **842** approximately 90 degrees counter-clockwise from the open position to a “closed” position. In this embodiment, in the closed position the knob handle orients approximately perpendicular to the outer edges of the end surface **835** and the tip **842-T** of the knob handle lies against a mark **831-M** on the left side of the protruded surface **831**.

During the tightening turn, the movement of the tightening features against each other determines the range of the turn and also creates the tension required for tightening the clamp. For example, the combination of the stopper and the stopper

teeth creates a stopping mechanism that limits the range of tightening turn, and the combination of the tension tang and the groove creates a clamping tension. Regarding the stopping mechanism, when the user turns the knob handle counter-clockwise, the stopper **847** moves counter-clockwise inside the lower right cut out until it reaches the side stopper tooth **834**. Side stopper tooth **834** thus stops the knob handle from turning further.

Regarding the clamping tension, the closing turn causes the sandwiched surfaces to push against the clamping surfaces. For example, on the rear end of the clamping mechanism, the bulge contacts the surface of the middle section. On the front side of the clamping mechanism, the knob cap **843** contacts the widened end surface, and more specifically, the tip of the tension tang **846** contacts the surface of the groove **832**. The surface of the groove is made with a gradual taper in its depth. That is, the upper part **832-U** of the groove is deeper than its lower part **832-L**. When the knob turns counter clockwise from the open position to the closed position, the tension tang **846**, which is in contact with the groove at the upper part **832-U**, moves to the lower part **832-L** of the groove. Due to the change of depth, with this movement the groove pushes the tension tang **846** forward. This forward push transfers through the middle rod **844** to the bulge **845**, thus clamping the middle section **825** and the widened end surface **835**. In effect, the tightening turn causes the effective total thickness of the sandwiched surfaces to increase, thus adding to the pressure between the sandwiched surfaces and the sandwiching surfaces of the clam.

In various embodiments, characteristics of the clamping mechanism and the clamped surfaces are such that the tightening turn locks the sandwiched surfaces to each other. In some embodiments, these characteristics include the amount of taper in the depth of the groove, the flexibility characteristics of the middle rod, and the friction coefficient between the two sandwiched surfaces, that is, the contacting surfaces of the body portion and the widened end surface. These characteristics are such that the tightening turn increases the contact friction between the two sandwiched surfaces by an amount that is sufficient for preventing the tube grasping mechanism **830** from moving with respect to the body portion **820**.

In some embodiments, a user can release the tube grasping mechanism by turning the knob clockwise from the closed position to the open position. Such opening turn causes the tension tang **846** to move from the shallower lower part **832-L** of the groove to the deeper upper part **832-U** of the groove. This move decreases the effective total thickness of the sandwiched surfaces, thus reducing the tension in the middle rod **844**. Accordingly, this untightening turn reduces the contact friction between the two sandwiched surfaces, allowing the tube grasping mechanism **830** to move with respect to the body portion **820**.

FIG. **11** shows a view **1100** of an assembled endotracheal tube holder **800** holding a tube **1110** against the face of a patient **1120**, according to an embodiment. In the view **1100**, a user has secured endotracheal tube holder **800** to the face of the patient **1120** by threading a band **1130** through band openings **860** and securing the band behind the head of the patient. In some embodiments, the band **1130** includes two complement mechanical attachment materials on its two surfaces. The user, after tightening the band **1130** around the patient's neck or head, can tie the band's end securely by fitting the two mechanical attachment mechanisms against each other. In some embodiments, the complement mechanical attachment materials include VELCRO® loop and hook materials. Further, in the embodiment shown in FIG. **11**, a

11

user has positioned the tube **1110** slightly to the left of the middle of the patient's mouth and has secured the tube in place by turning the knob handle to the closed position. In certain embodiments, tube holder **800** also includes two adhesive pads. Each of the adhesive pads attaches to one of the pad regions on one surface and to the face of the patient on the other surface. In various embodiments, the adhesive pads can be of different shapes, e.g., circular, oval, or rectangular. In some embodiments, adhesive pads are sized such that each fully covers the corresponding pad region.

It will be apparent to those skilled in the art that additional various modifications and variations can be made consistent with the present disclosure. Other embodiments consistent with the tube holder will be apparent to those skilled in the art from consideration of the specification and practice of the disclosure. It is intended that the specification and examples be considered as exemplary only, with a true scope and spirit of the disclosure being indicated by the following claims.

The invention claimed is:

1. An endotracheal tube holder comprising:

a tube grasping mechanism; and

a body portion, wherein the body portion is elongated and comprises an elongated opening in the form of an elongated slit along a horizontal axis of the body portion, the elongated slit permitting lateral adjustment and securing of an attachment mechanism to any location along the elongated slit, for adjustably securing the tube grasping mechanism to the body portion,

the attachment mechanism adjustably securing the tube grasping mechanism to the body portion, the attachment mechanism comprising:

a rod member configured to pass through the elongated opening;

a widened proximal body connected to a proximal end of the rod member; and

a widened distal body attached to a distal end of the rod member, having a size that prevents the widened distal body from passing through the elongated opening to secure the attachment mechanism to the body portion, and the widened distal body having a smooth, vertical surface parallel to and pressed against smooth, vertical surfaces on the body portion immediately below and above the elongated opening, whereby the pressing is predominantly accomplished through at least one force orthogonal to these surfaces.

2. An endotracheal tube holder comprising:

a tube grasping mechanism; and

a body portion, wherein the body portion is elongated and comprises an elongated opening in the form of an elongated slit along a horizontal axis of the body portion, the elongated slit permitting lateral adjustment and securing of an attachment mechanism to any location along the elongated slit, for adjustably securing the tube grasping mechanism to the body portion,

the attachment mechanism adjustably securing the tube grasping mechanism to the body portion, the attachment mechanism comprising:

a rod member configured to pass through the elongated opening;

a widened proximal body connected to a proximal end of the rod member; and

a widened distal body attached to a distal end of the rod member, having a size that prevents the widened distal body from passing through the elongated opening to secure the attachment mechanism to the body por-

12

tion, and wherein at least one end of the elongated slit includes a widened opening for receiving the widened distal body.

3. The tube holder of claim **2**, wherein the widened distal body has a spring like property along at least one dimension configured to being forcibly pushed through the widened opening and for locking behind the body portion.

4. The tube holder of claim **2**, wherein the widened distal body has a spring like property along at least one dimension configured to being forcibly pushed through a section of the elongated opening and for locking behind the body portion.

5. The tube holder of claim **1**, wherein the rod member comprises a threaded rod.

6. The tube holder of claim **5**, wherein at least one of the widened proximal body and the widened distal body includes a threaded locking cap such that rotation of the locking cap with respect to the threaded rod changes a distance between the widened proximal body and the widened distal body to clamp or release the attachment mechanism to or from the body portion.

7. The tube holder of claim **6**, wherein the tube grasping mechanism comprises a widened end surface in which a middle opening is formed for receiving the rod member, wherein the rod member is rigidly connected to the widened distal body at the distal end, and wherein the widened proximal body includes the locking cap, such that the threaded rod passes through the elongated opening and the middle opening and is threadably connected to the locking cap.

8. The tube holder of claim **2**, wherein the tube grasping mechanism comprises a widened end surface in which a middle opening is formed for receiving the rod member, wherein the widened end surface is for attaching to the body portion, and wherein the widened proximal body and the widened distal body sandwich between them the body portion and the widened end surface.

9. The tube holder of claim **2**, wherein the body portion is curved for conforming to the shape of the face of a patient.

10. The tube holder of claim **1**, wherein the tube grasping mechanism comprises an upper semicircular region and a lower semicircular region pivotably attached to the upper semicircular region.

11. The tube holder of claim **10**, wherein the upper semicircular region and the lower semicircular region comprise teeth to lock the lower semicircular region to the upper semicircular region and secure a tube therebetween.

12. The tube holder of claim **10**, wherein the lower semicircular region includes a tail end and the upper semicircular region includes a pincer configured to receive and lock the tail end and accordingly secure a tube between the upper and the lower semicircular regions.

13. The tube holder of claim **12** wherein the tail end is toothed on at least one surface.

14. The tube holder of claim **2**, wherein the body portion further comprises widened pad regions at opposite ends for lying against the face of a patient.

15. The tube holder of claim **14**, further comprising a band opening on each of the widened pad regions for receiving a flexible band for tying around the head or the neck of the patient.

16. The tube holder of claim **1**, wherein the body portion comprises a rigid material.

17. The tube holder of claim **2**, further comprising an arm that connects the tube grasping mechanism to the attachment mechanism.

18. The tube holder of claim **1**, wherein the elongated opening includes a toothed surface on at least one side.

13

19. An endotracheal tube holder, comprising:
 a tube grasping mechanism; and
 a body portion, wherein the body portion is elongated and
 comprises an elongated opening in the form of an elongated
 slit along a horizontal axis of the body portion, the elongated
 slit permitting lateral adjustment and securing of an attachment
 mechanism to any location along the elongated slit, for adjustably
 securing the tube grasping mechanism to the body portion,
 the tube grasping mechanism rigidly connected to the attachment
 mechanism adjustably securing the tube grasping mechanism to the
 body portion, the attachment mechanism comprising:
 a rod member that passes through the elongated opening;
 a widened proximal body connected to a proximal end of the rod
 member; and
 a widened distal body attached to a distal end of the rod member,
 having a size that prevents the widened distal body from passing
 through the elongated opening to secure the attachment mechanism
 to the body portion, and the widened distal body having a smooth,
 vertical surface parallel to and pressed against smooth, vertical
 surfaces on the body portion immediately below and above the
 elongated opening, whereby the pressing is predominantly accomplished
 through at least one force orthogonal to these surfaces.
20. The tube holder of claim 19, wherein the tube grasping
 mechanism comprises an upper semicircular region and a lower
 semicircular region pivotably attached to the upper semicircular
 region, and wherein the upper semicircular region and the lower
 semicircular region comprise teeth to lock the lower semicircular
 region to the upper semicircular region and secure a tube therebetween.
21. The tube holder of claim 19, wherein the rod member
 comprises a threaded body and wherein at least one end of the
 threaded body is connected to a threaded locking cap such that
 rotation of the locking cap with respect to the rod member
 changes a distance between widened surfaces on opposite sides
 of the elongated opening to clamp or release the attachment
 mechanism.
22. The tube holder of claim 21, wherein the rod member is
 rigidly connected to one of the widened surfaces on one side
 of the elongated opening.

14

23. An endotracheal tube holder, comprising:
 a tube grasping mechanism; and
 a body portion, wherein the body portion is elongated and
 comprises an elongated opening in the form of an elongated
 slit along a horizontal axis of the body portion, the elongated
 slit permitting lateral adjustment and securing of an attachment
 mechanism to any location along the elongated slit, for adjustably
 securing the tube grasping mechanism to the body portion,
 the attachment mechanism adjustably securing the tube grasping
 mechanism to the body portion, the attachment mechanism comprising:
 a rod member configured to pass through the elongated opening;
 a widened distal body attached to a distal end of the rod member,
 wherein at least one end of the elongated slit of the elongated
 slit includes a widened opening for receiving the widened distal
 body.
24. An endotracheal tube holder, comprising:
 a tube grasping mechanism; and
 a body portion, wherein the body portion is elongated and
 comprises an elongated opening in the form of an elongated
 slit along a horizontal axis of the body portion, the elongated
 slit permitting lateral adjustment and securing of an attachment
 mechanism to any location along the elongated slit, for adjustably
 securing the tube grasping mechanism to the body portion,
 the tube grasping mechanism rigidly connected to the attachment
 mechanism adjustably securing the tube grasping mechanism to the
 body portion, the attachment mechanism comprising:
 a rod member that passes through the elongated opening;
 a widened proximal body connected to a proximal end of the rod
 member; and
 a widened distal body attached to a distal end of the rod member,
 having a size that prevents the widened distal body from passing
 through the elongated opening to secure the attachment mechanism
 to the body portion, and wherein at least one end of the elongated
 slit includes a widened opening for receiving the widened distal
 body.
